Winter Semester 2025/26

Some terminology

- . For any pair of nodes u and v in a directed graph
- A directed graph is strongly connected if there is a directed path between u and v to u
 A directed graph is somi-connected if there is a directed path between u to

 - rected graph obta
 - replacing all edges with undirected edges result in a connected graph

Transitive closure

- · We know that graph traversals ans wer reachability gu efficiently
- \star Pre-computing all nodes reachable from every other node is beneficial in some applications
- unsitive closure of a graph is another graph where
- The set of nodes are the same as the original graph
 There is an edge between two nodes u and v if v is reachable from u
- · For an undirected graph, transitive closure can be computed by computing

Floyd-Warshall algorithm

- ember that transitive closure of a graph is an Floyd-Warshall algorithm is an iterative algorithm that computes the transitive closure in n iterations
- . The algorithm starts with setting transitive closure to the
- original graph
 For k = 1 ... n
- Add a directed edge (v_i,v_j) to transitive closure if it already contains both (v_i,v_k) and (v_k,v_j)
- It is efficient if graph is implemented with an adjacency matrix and it is not sparse

Floyd-Warshall algorithm

Time complexity is O(n³)

- T = [row[:] for row in G]
- T = [row[:] for row in G]
 for k in range(n):
 for in range(n):
 for in range(n):
 if i = k: continue
 for j in range(n):
 if j = k:
 continue
 T[i][j] = T[i][j] or \
 T[i][k] and T[k][j]
- Note that in a dense graph m is O(n²) A version of this algorithm is also used for finding shortest paths in weighted graphs (later in the

Compare with repeated trave O(n(n+m))

Directed acyclic graphs

COURSE DESCRIPTION PREREQS COMPUTER CPSC 452 INTERMEDIATE COMPLER DESIGN, WITH A FOCUS ON DEPENDENCY RESOLUTION.

Directed graphs

- · Directed graphs are graphs with directed edges · Some operations are more meaningful or challenging in directed graph:
- . We will cover some of these operations, and some interesting sub-types of
- directed graphs

 Transitive closure

 Directed acyclic graphs

 Topological ordering

Checking strong connectivity

- independently from each node (strongly connected if all traversals visit all nodes) Time complexity: O(n(n+m)) A better one
- * Time complexity: O(n+m)

- - reverse all edges, traverse again
 intuition: if there is a reverse path from D to A then D is reachable from A
- Note: we do not need to copy the graph, we only need to do 'reverse edge' queries

Computing transitive closure on directed graphs

- A straightforward algorithm:
 - m m graph traversals, from each node in the graph, add an edge between the start node to any node discovered by the travers time complexity is O(n(n+m))
- · Floyd-Warshall algorithm is another well-known algorithm
- efficiently in some settings

Floyd-Warshall demonstration

Directed acyclic graphs

- * Directed acyclic graphs (DAGs) are directed graphs without cycles DAGs have many practical applications (mainly, dependency graphs)
 - Prerequisites between courses in a study program
 Class inheritance in an object-oriented program

 - Scheduling constraints over tasks in a project
 Dependency parser output (generally trees, but can also be more general DAGs)
 A compact representation of a list of words:
 - - -1-

DAG exammple

Topological order Topological order example A topological ordering of a directed graph is a sequence of nodes such that for every directed edge (u, v) u is listed before v
 A topological ordering lists 'prerequisities' of a node before listing the node itself Intro to CL Tex DSA 3 There may be multiple topological orderings In the course prerequisite example, a topological ordering lists any accept order that the courses can be taken Intro to Ling. Topological sort Topological sor topo, ready = [], []
incount = ()
for u in nodes:
incount [u] = u.indegree()
if incount [u] = 0:
ready.append(u)
while let(ready) > 0:
u = ready.pop()
top vp. node()
for v in neighbors():
incount[v] = 0:
incount[v] = 0:
if incount[v] = 0:
ready.append(v) D C B E G A D H Keep a record of the number of unprocessed incoming edges G A node is ready to be placed in the sorted list if there no unprocessed incoming edges * Running time is O(n+m) If the topological ordering does not cont all the edges, the graph includes a cycle · H Summary Acknowledgments, credits, references Some operations on directed graphs are more challenging
 We covered Finding strongly connected components
 Finding the transitive closure of a digraph
 DAGs and topological ordering Goodrich, Michael T., Roberto Tamassia, and Michael H. Goldwasser (2013) Data Structures and Algorithms in Python. John Wiley & Sons, Incorporated. is • Reading on graphs: Goodrich, Tama ssia, and Goldwasser (2013, chapter 14) More on graphs: shortest paths, minimum spanning trees
